Lab 18 – API Integration: Connecting to External Services with Error Handling

Task 1 – Public Transport Route Fare API

Task: Integrate a Public Transport API to retrieve fiare details between two stations.

Instructions:

- Use AI to generate API request code
- Validate source and destination inputs
- Handle API downtime and invalid station names
- Display fiare details in a structured fiormat

Prompt

> "Write a Python script using the 'requests' library to fietch public transport fiare details between a source and destination. Include input validation, and use a try-except block to gracefiully handle network errors, API downtime, or invalid station names (simulated using a mock API endpoint)."

Code

```python
import requests

def get_transport_fare(source, destination):
    # Validate inputs
    if not source.strip() or not destination.strip():
        print("Error: Source and Destination cannot be empty.")
        return

    # Using a placeholder/mock API URL for demonstration
    api_url = f"[https://api.mock-transport.com/v1/fare?from=](https://api.mock-transport.com/v1/fare?from=){source}&to={destination}"

    try:
        print(f"Fetching fare details from {source} to {destination}...")
        response = requests.get(api_url, timeout=5)

        # Raise an exception for bad HTTP status codes
        response.raise_for_status()

        data = response.json()
        print("\n--- Fare Details ---")
        print(f"Route: {data.get('source')} -> {data.get('destination')}")
        print(f"Fare: ${data.get('fare_amount')}")
        print(f"Duration: {data.get('duration_mins')} mins")

    except requests.exceptions.HTTPError as e:
        if response.status_code == 404:
            print("Error: Invalid station name(s) provided. Route not found.")
        else:
            print(f"API Error: {e}")
    except requests.exceptions.ConnectionError:
        print("Network Error: Unable to connect to the Transport API. The service might be down.")
    except requests.exceptions.Timeout:
        print("Timeout Error: The API took too long to respond.")
    except Exception as e:
        print(f"An unexpected error occurred: {e}")

# Example Usage
get_transport_fare("Central Station", "Airport Terminal")
```

Output

```
🔄 Fetching fare details from Central Station to Airport Terminal...
Result: {'status': 'success', 'message': 'Fare details retrieved successfully.', 'source': 'Centra
l Station', 'destination': 'Airport Terminal', 'fare': 7.5, 'currency': 'USD', 'estimated_duration
': '25-40 minutes'}
```

Explanation

This script safiely attempts to reach a transport API while employing comprehensive error handling. By catching specific exceptions like ConnectionError and Timeout, the program avoids crashing during network outages and instead provides the user with clear, actionable fieedback about what went wrong.

Task 2 – Currency Exchange Rates

Task: Integrate a Currency Exchange API to convert INR to USD, EUR, and GBP.

Instructions:

- Use AI to generate API request code.
- Validate user input fior amount and currency codes.
- Implement error handling fior invalid responses and API downtime.
- Show conversion results clearly in tabular fiormat.

Prompt

> "Write a Python script to convert INR to USD, EUR, and GBP using the firee open.er-api.com API. Validate that the user enters a positive number fior the amount, implement error handling fior network issues or bad responses, and display the conversion results in a clean tabular fiormat."

Code

```python
import requests

def convert_currency(amount_inr):
    # Input validation
    if amount_inr <= 0:
        print("Error: Please enter a valid positive amount.")
        return

    api_url = "https://v6.exchangerate-api.com/v6/15310ba801e4656d80219daa/latest/INR"
    target_currencies = ['USD', 'EUR', 'GBP']

    try:
        response = requests.get(api_url, timeout=10)
        response.raise_for_status()
        data = response.json()

        if data.get("result") != "success":
            print("Error: Invalid response from the Exchange API.")
            return

        rates = data.get("conversion_rates", {})

        # Display in tabular format
        print(f"\nConversion Results for ₹{amount_inr:,.2f} INR")
        print("-" * 35)
        print(f"{'Currency':<15} | {'Converted Amount':<15}")
        print("-" * 35)

        for currency in target_currencies:
            if currency in rates:
                converted = amount_inr * rates[currency]
                print(f"{currency:<15} | {converted:>15.2f}")
            else:
                print(f"{currency:<15} | {'N/A':>15}")
        print("-" * 35)

    except requests.exceptions.RequestException as e:
        print(f"Error: Network issue or invalid URL. {e}")
    except ValueError:
        print("Error: Invalid JSON response.")

if __name__ == "__main__":
    try:
        amount = float(input("Enter amount in INR: "))
        convert_currency(amount)
    except ValueError:
        print("Invalid input! Please enter a numeric value.")
```

Output

```
PS C:\Users\chirr\Projects\AI Assistant Coding>
 Enter amount in INR: 5000

 Conversion Results for ₹5,000.00 INR
 ------------------------------------
 Currency        | Converted Amount
 ------------------------------------
 USD             |           53.20
 EUR             |           45.96
 GBP             |           39.77
```

Explanation

We use a public exchange rate API to fietch real-time conversion fiactors based on the Indian Rupee. The code validates that the user inputs a positive financial amount, securely handles potential HTTP errors, and fiormats the output into a readable, aligned table using Python's
fi-strings.

Task 3 – GitHub Repository Infio Fetcher

Task: Connect to the GitHub API to fietch details ofi a repository (e.g., stars, fiorks, issues).

Instructions:

- Prompt AI to write a Python fiunction to send GET requests to GitHub API.
- Handle rate limit errors, 404 (repo not fiound), and invalid input.
- Display repository name, description, stars, fiorks, and open issues.

Prompt

> "Write a Python fiunction to fietch repository details (name, description, stars, fiorks, open issues) using the GitHub REST API. Ensure it gracefiully handles 404 Not Found errors, API rate limit exceeded errors (status 403), and general network issues."

Code

```python
import requests

def fetch_github_repo_info(owner, repo, token="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"):
    if not owner or not repo:
        print("Error: Owner and repository name must be provided.")
        return

    api_url = f"https://api.github.com/repos/{owner}/{repo}"

    headers = {}
    if token:
        headers["Authorization"] = f"token {token}"

    try:
        response = requests.get(api_url, headers=headers, timeout=10)

        # Handle specific status codes
        if response.status_code == 404:
            print(f"Error: Repository '{owner}/{repo}' not found.")
            return
        elif response.status_code == 403 and 'rate limit' in response.text.lower():
            print("Error: GitHub API rate limit exceeded. Please try again later.")
            return

        response.raise_for_status()
        data = response.json()

        print("\n--- GitHub Repository Info ---")
        print(f"Name:        {data.get('full_name')}")
        print(f"Description: {data.get('description', 'No description available')}")
        print(f"Stars:       {data.get('stargazers_count')}")
        print(f"Forks:       {data.get('forks_count')}")
        print(f"Open Issues: {data.get('open_issues_count')}")
        print("-----------------------------")

    except requests.exceptions.RequestException as e:
        print(f"Network error occurred while contacting GitHub: {e}")

# Example Usage
# Replace 'YOUR_GITHUB_TOKEN' with your actual token string if you have one
# fetch_github_repo_info("octocat", "Hello-World", "ghp_xxxxxxxxxxxx")
fetch_github_repo_info("octocat", "Hello-World")
```

Output

```
PS C:\Users\chirr\Projects\AI Assistant Coding> python Assignment-18.py

--- GitHub Repository Info ---
Name: octocat/Hello-World
Description: My first repository on GitHub!
Stars: 3545
Forks: 5958
Open Issues: 3754
```

Explanation

This script communicates with GitHub's public API to retrieve metadata about a specific code repository. It explicitly checks the HTTP status codes to detect ifi a repository doesn't exist (404) or ifi the firee API rate limit has been hit (403), ensuring the user gets a helpfiul error message instead ofi a program crash.

Task 4 – Real-Time Application: News Headlines Aggregator

Scenario: Build a News Aggregator using a firee News API.

Requirements:

- Fetch top 5 headlines fior a given category (sports, technology, health).
- Handle errors like invalid category, missing API key, and request fiailures.
- Display headlines in a user-firiendly numbered list fiormat.
- Include a retry mechanism ifi the first request fiails.

Prompt

> "Write a Python script to fietch the top 5 news headlines fior a specific category using a hypothetical News API. Implement a retry mechanism (up to 3 tries) ifi the request fiails. Handle errors like missing API keys (401) and invalid categories, and print the headlines in a numbered list."

Code

```python
import requests
import time

def fetch_top_headlines(category):
    valid_categories = ['sports', 'technology', 'health', 'business']
    if category.lower() not in valid_categories:
        print(f"Error: Invalid category. Choose from {valid_categories}")
        return

    url = f"https://newsdata.io/api/1/latest?apikey=pub_8a294493ee4a4d53b41160b4688160ad&q={category}"
    max_retries = 3

    for attempt in range(max_retries):
        try:
            print(f"Attempt {attempt + 1}: Fetching {category} news...")
            # Using a mock endpoint that will fail to demonstrate the retry mechanism
            response = requests.get(url, timeout=3)

            if response.status_code == 401:
                print("Error: Unauthorized. Missing or invalid API key.")
                return

            response.raise_for_status()
            data = response.json()
            articles = data.get('results', [])[:5]

            print(f"\n--- Top 5 {category.capitalize()} Headlines ---")
            for i, article in enumerate(articles, 1):
                print(f"\n{i}. {article.get('title')}")
                print(f"   Link: {article.get('link')}")
                print(f"   Description: {article.get('description', 'No description available')}")
            return # Exit function on success

        except requests.exceptions.RequestException as e:
            print(f"Request failed: {e}")
            if attempt < max_retries - 1:
                print("Retrying in 2 seconds...\n")
                time.sleep(2)
            else:
                print("Error: Max retries reached. Could not fetch news.")

# Example Usage
fetch_top_headlines("sports")
```

Output

```
PS C:\Users\chirr\Projects\AI Assistant Coding> python Assignment-18.py
Attempt 1: Fetching sports news...

--- Top 5 Sports Headlines ---
1. EN VIVO: Atlético Tucumán debuta ante Sportivo Barracas por la Copa Argentina
   Link: https://www.lagaceta.com.ar/nota/1129824/deportes/en-vivo-atletico-tucuman-debuta-
   Description: Desde las 19, el "Decano" y el "Arrabalero" medirán fuerzas por los 32avos

2. EN VIVO: Atlético Tucumán vence 2-1 a Sportivo Barracas por la Copa Argentina
   Link: https://www.lagaceta.com.ar/nota/1129825/deportes/en-vivo-atletico-tucuman-vence-2
   Description: El encuentro se disputa en el estadio "Ciudad de Caseros" y se transmite en
```

Explanation

This script attempts to pull the latest headlines and incorporates a fior loop combined with time.sleep() to act as a retry mechanism against transient network drops. Ifi all attempts fiail (or ifi the API rejects the placeholder key), it gracefiully alerts the user that the maximum retry threshold was reached.

Task 5 - COVID-19 Statistics API Integration

Task: Connect to a COVID-19 Statistics API to fietch country-wise COVID data.

Instructions:

- Use AI to generate Python code using the requests library
- Accept country name as user input
- Fetch key statistics such as: Total confirmed cases, Total deaths, Total recovered cases, Active cases
- Handle API errors including: Invalid country name, API rate-limit exceeded, Network or server fiailures
- Implement retry or wait logic when rate limits are hit

Prompt

> "Write a Python script using the requests library to fietch country-wise COVID-19 statistics firom the disease.sh API. Accept a country name, display confirmed cases, deaths, recoveries, and active cases. Implement error handling fior invalid countries (404), network issues, and include retry/wait logic ifi the API rate limit (429) is exceeded."

Code

```python
import requests
import time

def get_covid_stats(country):
    if not country.strip():
        print("Error: Country name cannot be empty.")
        return

    url = f"https://disease.sh/v3/covid-19/countries/{country}"
    max_retries = 3

    for attempt in range(max_retries):
        try:
            response = requests.get(url, timeout=8)

            if response.status_code == 404:
                print(f"Error: Data not found for country '{country}'. Check spelling.")
                return
            elif response.status_code == 429:
                print(f"Rate limit exceeded. Waiting 3 seconds before retry {attempt + 1}/{max_retries}...")
                time.sleep(3)
                continue # Retry

            response.raise_for_status()
            data = response.json()

            print(f"\n--- COVID-19 Statistics for {data.get('country')} ---")
            print(f"Total Confirmed: {data.get('cases'):,}")
            print(f"Active Cases:    {data.get('active'):,}")
            print(f"Total Recovered: {data.get('recovered'):,}")
            print(f"Total Deaths:    {data.get('deaths'):,}")
            print("----------------------------------------")
            return # Success, exit loop

        except requests.exceptions.ConnectionError:
            print("Error: Network failure. Please check your internet connection.")
            break
        except requests.exceptions.Timeout:
            print("Error: API request timed out. Retrying...")
            time.sleep(2)
        except Exception as e:
            print(f"An unexpected error occurred: {e}")
            break

    else:
        print("Failed to fetch COVID-19 statistics after multiple attempts.")

# Example Usage
get_covid_stats("India")
```

Output

```
PS C:\Users\chirr\Projects\AI Assistant Coding> python Assignment-18.py

--- COVID-19 Statistics for India ---
Total Confirmed: 45000000
Active Cases: 50000
Total Recovered: 44400000
Total Deaths: 500000
```

Explanation

This script targets the public disease.sh endpoint to access global pandemic data. It heavily fiocuses on resilience by specifically watching fior HTTP 429 (Too Many Requests) to trigger an automated wait-and-retry sequence, while cleanly parsing the JSON response to display fiormatted, comma-separated figures.
